ABSTRACT: The fruit of 'Taquari' have attractive appearance, with intense yellow flesh, pleasant taste and absence of fibers, which makes it a potential material for, after a series of studies, being released as a variety. For biometrics, 50 mature fruit were used the results (average of three samples) were evaluated by descriptive statistics using central trend (average) and variability of data (standard error and coefficient of variation). For the germination test, the seeds were extracted from ripe fruit and dried; subsequently, they were germinated in sachets containing the mixture soil:sand:corral manure (3:1:1) as substrate, evaluating seedling emergence and polyembryony. The design was in randomized blocks and 5 treatments were studied, with 5 replicates each and 10 seeds per replicate. The percentage data were transformed into arc-sen, submitted to analysis of variance and the means, to Tukey test at 5% probability. For fruit quality characterization, 12 ripe fruits were used, separated into 3 lots with 4 fruit, using a completely randomized design. The fruit were characterized regarding firmness, peel and pulp color, soluble solids, titratable acidity, pH, ascorbic acid and respiratory rate. We conclude that the 'Taquari' has fruit with interesting characteristics for the Brazilian market and there is a better seedling emergence in the absence of seed coat, but with a greater occurrence of polyembryony. For quality characterization, the fruit present parameters such as soluble solids and titratable acidity similar to the main varieties of mangoes sold in the country, but with emphasis to the high ascorbic acid content detected.

KEYWORDS: Chemical characterization. *Mangifera indica* L. Polyembryony. Propagation.

INTRODUCTION

Mango (*Mangifera indica* L.), which belongs to the family Anacardiaceae, is among the tropical fruits with the highest economic expression in the Brazilian and International markets (1.132.463 tons), not only for being exotic in terms of appearance and flavor, but also for being a rich source of carotenoids and carbohydrates (SIVANKALYANI et al., 2016; FAO, 2017).

Among the cultivars with commercial importance, 'Tommy Atkins', with 48,025 tons in 2014 is the most cultivated and exported in the country because of its good productivity, ability to adapt to different cultivation environments, higher tolerance to certain diseases, besides presenting fruit with quality and good post-harvest conservation (AGRIANUAL, 2017).

Seed germination is regarded as the resumption of growth from the embryonic axis, which is paralyzed at the final stages of the maturation process, but develops when stimulated by environmental conditions, then occurring coat rupture by the radicle. It is a critical step of the plant biocycle, because of its association with several factors of extrinsic nature, such as environmental

factors, and intrinsic nature, related to physiometabolic factors. (HARTMANN et al., 2010).

The morphologic characterization of the plant provides an identity for each material by the use of descriptors that enable the study of the genetic variability; therefore, these characters guarantee a signature of plant species identity, as well as varietal and genetic purity, also being used for many researchers for germplasm characterization and, although there are more advanced techniques, the techniques for morphological characterization are more accessible and anticipate other techniques, thus making it possible to direct the work to be developed with more sophisticated descriptors, such as molecular markers (GUSMÃO et al., 2016).

Thus, the biometric characterization of fruits can be used as an indicative of the genetic variability to be explored in breeding programs, providing important information, thus allowing the differentiation of species of the same Genus, determining their conditions of weight, width, length, diameter, volume, being consolidated as a tool for fruit classification, with importance for taxonomy, in the identification of varieties and to

verify the occurrence of phenotypic variations (SOUZA et al., 2017).

In fruit maturation, in general, there are transformations which reflect in changes in their quality characteristics (BURDON et al., 2017), such as color, texture, flavor, aroma, soluble solids content, titrable acidity, pH, respiratory activity, among others, which indicate maturation and further senescence.

Fruit quality cannot be measured only by the physical characteristics, such as size and weight, since not always the fruits with good appearance present organoleptic attributes and desirable yields for the market, with good conservation during storage. Therefore, it is necessary that the fruits be evaluated regarding quality characteristics, aiming at granting the best post-harvest conservation and meeting consumers' demands (ZUFFO et al., 2016)

Facing the importance of the mango culture and the possibility of emergence of a new material, this work aimed to evaluate seed germination by seedling emergence, in the presence and absence of coat, besides performing the biometric characterization of fruit and seeds of the 'Taquari' fruit tree, as well as performing the physical and quality characterization of the fruit, allowing a broader knowledge and comparison with the most traditional and most cultivated cultivars.

MATERIAL AND METHODS

Biometric characterization

For the biometric characterization, 50 ripe fruit were used, collected from an adult plant of 'Taquari' fruit (material originated from the seed, without data on the parental plants) and the following were obtained: masses from fruit, peel, kernel and seed (grams, in a digital scale with precision of 0.001g); length and width of fruit, kernel and seed (cm, with the aid of a graduated ruler, measuring the width in the central part and considering as length the distance between the basal and apical portions); and pulp percentage. The results (average of three samples) were evaluated by descriptive statistics using central trend (average) and variability of data (standard error and coefficient of variation). The number of classes for each parameter evaluated was determined, the amplitude of the data was calculated, as well as the length of each interval of class, determining the superior and inferior limits. Tables of frequency were used to organize the data, then correlating the classes of values and the frequency of the number of values that fit into each class. For all characters evaluated, three classes were determined, namely,

for mass: light, medium and heavy; for length: short, medium and long; for width: narrow, medium and large; and for pulp percentage: low, medium and high.

Germination test

For the germination test, the seeds (with coat) were extracted from ripe fruit, washed, dried in the shadow and, to germinate, placed in polyethylene sachets with capacity for 1.5 liters, containing as substrate a mixture of soil + sand + corral manure, in the proportion 3:1:1. For the treatment without coat, after drying the kernel, it was carefully removed with the use of pruning shears. The following characters were evaluated: a) seedling emergence (for 12 weeks), in percentage; and b) polyembryony (for nine weeks, starting on the fourth week after emergence). The design was in randomized blocks, using five repetitions with 10 seeds for each treatment. For the emergence, the percentage data were transformed into arc-sen and subjected to the analysis of variance and the means, to the Tukey test at $p > 0.05$ probability. For polyembryony, the data were analyzed establishing the confidence interval by the t test at 5% probability. The interval was determined using the equation: $IC = (t \times desvipad) / raiznr$, in which IC = confidence interval; t = tabulated t value, $p > 0.05$ probability; $desvipad$ = standard deviation; and $raiznr$ = square root of the number of repetitions.

Physical and quality characterization

For the physical and quality characterization of the fruit, 12 ripe fruits were used, separated into 3 lots with 4 fruit, collected from an adult plant of the 'Taquari'. They were washed with neutral detergent, washed in running water and sanitized in Sumaveg® solution (Active principle: Sodium Dichloroisocyanurate Dihydrate, Active Chlorine Content = 3% minimum) at 200 mg L⁻¹ of free chlorine, for 5 minutes.

After dried at room temperature, they were selected based on coloration, size and absence of defects and symptoms of disease, and analyzed according to the following parameters: fruit respiratory rate (ml CO₂ kg⁻¹h⁻¹) in a chromatograph of the model Trace GC Ultra, Thermo Scientific; fruit fresh mass, expressed in grams, quantified in a scale with precision of 0.01 g, pulp firmness, in Newtons, determined at the equatorial region of the fruit after peel removal, using a penetrometer of the brand Digital Force Gauge, model: IP-200 with tip of 8 mm; peel and pulp coloration, using a colorimeter MINOLTA CR 400, brand KONICA MINOLTA, where the values of L*, h* and C* were

determined, with L* representing: luminosity (100 = white; 0 = black), h*: Hue Angle and C*: chromaticity (Minolta, 2007); titrable acidity of the fruit, determined in 10 grams of ground pulp, diluted in 50 mL of distilled water, by titration with 0.1 M NaOH; for the quantification, the methodology described by AOAC was employed (1997); soluble solids contents of the fruit according to AOAC (1997), from the ground fruit pulp, using gauze to obtain the liquid, and quantified in a digital refractometer of the model PR 101, with the results expressed in °Brix; fruit pH, determined using a pH meter of the model Tec-3MP, based on the technique of AOAC (1997), and ascorbic acid

content, determined as indicated by AOAC (1997) from 10 g of ground pulp, and the results were expressed in mg ascorbic acid g⁻¹ of pulp.

RESULTS AND DISCUSSION

Biometric characterization

Based on the biometry, the fruit can be classified as long (Table 1) (12.86 to 13.90 cm), with medium width (Table 2) of 6.3 to 7.1 cm, peel mass (Table 3) between 20.41 and 30.76 grams and medium pulp percentage (Table 4) of 70.16 to 76.45%, resulting in a total mass (Table 5) between 203.33 and 241.66 grams.

Table 1. Length class of the 'Taquari', considering fruit percentage in each frequency interval.

Fruit length class	Frequency interval (cm)	% of fruit
Short	10.80 to 11.83	32
Medium	11.83 to 12.86	28
Long	12.86 to 13.90	40
Standard deviation	0.87	

Table 2. Width class of 'Taquari', considering the percentage of fruit in each frequency interval.

Fruit width class	Frequency interval (cm)	% of fruit
Narrow	5.5 to 6.3	24
Medium	6.3 to 7.1	56
Large	7.1 to 7.9	20
Standard deviation	0.53	

Table 3. Peel mass class of 'Taquari', considering the percentage of fruit in each frequency interval.

Peel mass class	Frequency interval (grams)	% of fruit
Light	10.06 to 20.41	12
Medium	20.41 to 30.76	64
Heavy	30.76 to 41.1	24
Standard deviation	5.62	

Table 4. Pulp percentage class of 'Taquari', considering the percentage of fruit in each frequency interval.

Pulp percentage class	Frequency interval (%)	% of fruit
Low	63.87 to 70.16	14
Medium	70.16 to 76.45	72
High	76.45 to 82.74	14
Standard deviation	3.34	

Table 5. Mass class of 'Taquari', considering the percentage of fruit in each frequency interval.

Fruit mass class	Frequency interval (grams)	% of fruit
Light	165.00 to 203.33	26
Medium	203.33 to 241.66	58
Heavy	241.66 to 280.00	16
Standard deviation	23.73	

Around 60% of the kernels have length (Table 6) between 9.3 and 10.4 cm and width (Table 7) between 3.1 and 3.4 cm, with mass (Table 8) between 27.60 and 34.14 grams. Regarding the

seeds, they can be considered long (Table 9) (7.34 to 8.00 cm), with width (Table 10) between 2.5 and 3.0 cm and mass (Table 11) between 17.14 and 21.21 grams.

Table 6. Length class of 'Taquari', kernel, considering the percentage of fruit in each frequency interval.

Kernel length class	Frequency interval (cm)	% of fruit
Short	8.2 to 9.3	34
Medium	9.3 to 10.4	60
Long	10.4 to 11.5	6
Standard deviation	0.59	

Table 7. Width class of 'Taquari' kernel, considering the percentage of fruit in each frequency interval.

Kernel width class	Frequency interval (cm)	% of fruit
Narrow	2.8 to 3.1	26
Medium	3.1 to 3.4	40
Large	3.4 to 3.7	34
Standard deviation	0.21	

Table 8. Mass class of 'Taquari' kernel, considering the percentage of fruit in each frequency interval.

Kernel mass class	Frequency interval (grams)	% of fruit
Light	21.06 to 27.60	20
Medium	27.60 to 34.14	70
Heavy	34.14 to 40.68	10
Standard deviation	3.58	

Table 9. Seed length class of 'Taquari', considering the percentage of fruit in each frequency interval.

Seed length class	Frequency interval (cm)	% of fruit
Short	6.00 to 6.67	22
Medium	6.67 to 7.34	36
Long	7.34 to 8.00	42
Standard deviation	0.52	

Table 10. Seed width class of 'Taquari', considering the percentage of fruit in each frequency interval.

Seed width class	Frequency interval (cm)	% of fruit
Narrow	2.0 to 2.5	12
Medium	2.5 to 3.0	70
Large	3.0 to 3.5	18
Standard deviation	0.35	

Table 11. Seed mass class of 'Taquari', considering the percentage of fruit in each frequency interval.

Seed mass class	Frequency interval (grams)	% of fruit
Light	13.07 to 17.14	16
Medium	17.14 to 21.21	54
Heavy	21.21 to 25.29	30
Standard deviation	2.65	

When the ratio of the values of fruit length and width is calculated, it can be noticed that the values range from 1.76 to 1.96, evidencing the elongated shape. Fruit mass values for 'Taquari' were lower than those observed for the fruit of 'Palmer' (500g), 'Haden' (350g - 680g) and 'Tommy Atkins' (460g), varying between 165 and

280 grams in this study, which can be interesting for the market, since, according to the Brazilian Packaging Association (2015), the search for packages with smaller fruits and individual or fractional portions has risen considerably in the last years, which is due to the structuring of the Brazilian adult, of whom, according to the research,

30% live alone or as a couple without children (JAIME et al., 2015) and, although the fruit are smaller, pulp percentage is high – even in fruit classified as having a low pulp percentage presented more than 63% and the fruit with the highest expression, with more than 82% of pulp, an extremely positive characteristic.

Several works have been performed with biometrics of fruit trees, allowing the characterization and distinction of materials, using morphological characters, such as in breadfruit (*Artocarpus altilis*) (BEZERRA et al., 2017), taperebazeiro (*Spondias mombin* L.) (BAIA et al.,

2015), porangaba (COSSA et al., 2016), buriti (*Mauritia flexuosa* L. f.) (MATOS et al., 2014) and cocoa (*Theobroma cacao*) (VENIAL et al., 2017), which evidences the importance of this kind of marker in fruticulture, allowing a better characterization of fruits with possibility of market.

Germination test

Regarding germination, measured by the emergence of seedlings, it is observed, in Figure 1, that regardless of the treatment, it started on the third week of sowing.

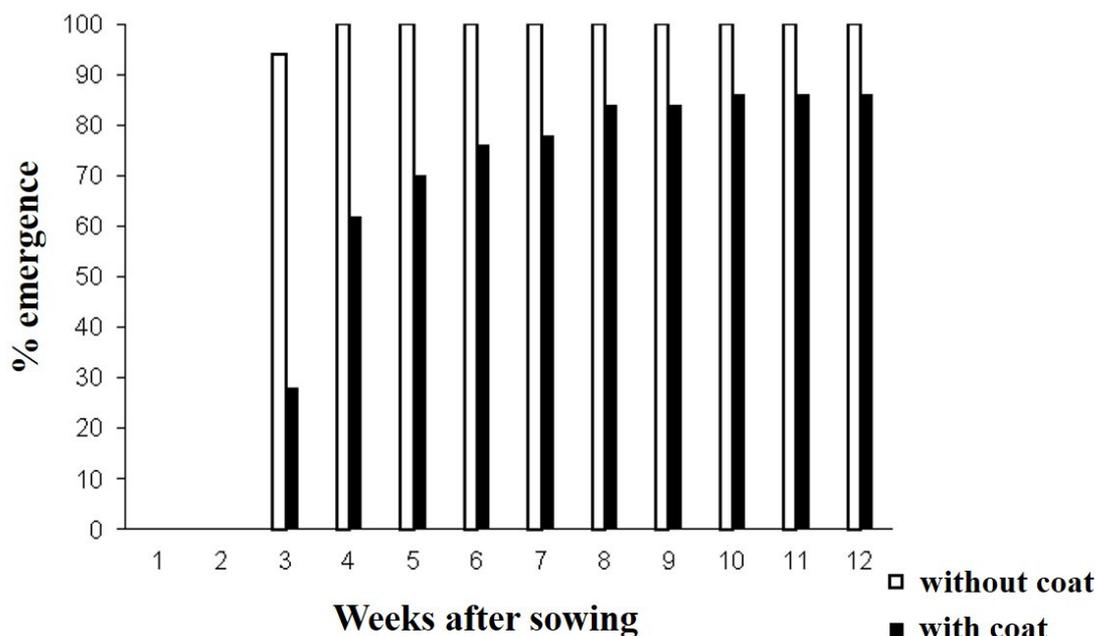

Figure 1. Percentage of emergence of 'Taquari' seedlings, with and without coat covering the seed.

For the treatment without coat on the seed, a higher precocity is noted, with 100% of emergence already on the fourth week after sowing, whereas for the treatment with coat, there were 86% de emergence only on the ninth week, which is not interesting for the producer, increasing the costs with seedling in the nursery.

Some studies show that the coat, besides having a protective function to the embryo, presents some other purposes, such as: keeping the cotyledons together; acting as a barrier for fungi, insects and microorganisms; regulating the speed of seed rehydration, gas exchanges and seed germination and, in some cases, it can act as a barrier for germination, making the development and emergence more difficult (CARVALHO and NAKAGAWA, 2012), as verified in the present work with the 'Taquari'.

In Table 12, it is possible to verify that there was a significant difference between the treatments (seed with and without coat), with the highest emergence rate observed when the coat is removed from the seed, as expected, since a physical barrier to embryo development is eliminated, besides facilitating the process of water absorption, fundamental for germination and emergency.

A higher percentage of plants with polyembryony is observed, in Table 13, when the coat was removed from the seed (70.37%) in comparison to the seedlings originated from seeds that germinated with the coat (34.15% of polyembryony), a result that was also expected, since the removal of the coat/kernel provides a higher ease for embryo germination and emergence, which do not need to resist any higher physical barrier.

Table 12. Results of the statistical analysis for the percentage of emergence of ‘Taquari’ seedlings, for seeds with and without coat, at the end of 12 weeks.

Treatment	% emergence
Seed with coat	74.0 b
Seed without coat	99.4 a
CV	7.28
DMS	6.13

Means followed by the same letter do not differ significantly by the Tukey test at 5% probability.

Table 13. Percentage of seedlings with polyembryony in ‘Taquari’ tree, in seeds with and without coat.

Treatments (T)	Polyembryony (%)
Seed without coat	70.37 a
Seed with coat	34.15 b
F TEST	
Treatments	30.254 **
CV (%)	19.03

Means followed by the same letter do not differ significantly by the Tukey test at 5% probability.

Regarding the number of seedlings that emerged from each seed, around three to four were registered, for seeds with and without coat, respectively. Furthermore, it was also verified that in the seeds without coat, the maximum expression

of polyembryony was reached on the fourth week after the beginning of seedling emergence, whereas for the seeds with coat, the maximum polyembryony only happened on the seventh week (Figure 2).

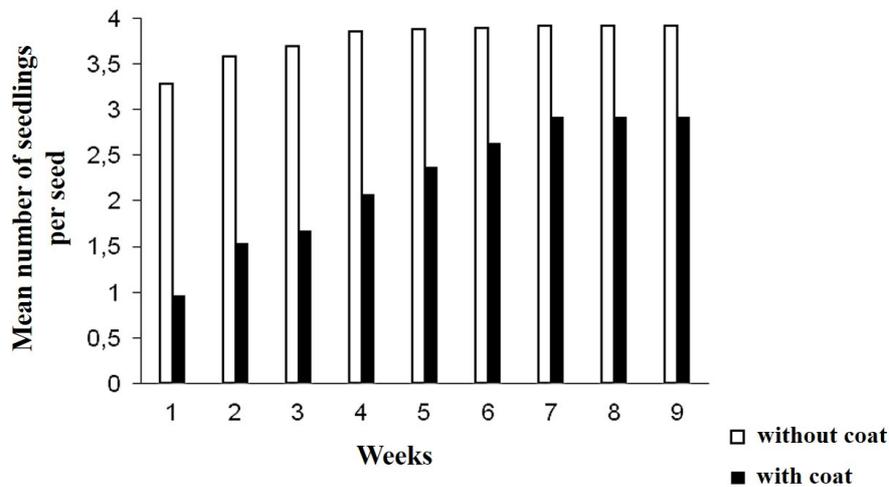

Figure 2. Mean number of seedlings emerged per seed, with and without coat, for ‘Taquari’.

Similar results, for both emergence and polyembryony, were also observed in works with the rootstock cultivars ‘Manguita’ and ‘Espada’ (SANTOS et al., 2009).

Quality characterization

According to the quality characterization of the fruit (Table 14), the mean weight registered per fruit was 246.7 g, and the firmness measured in fruit

pulp was 18 N. The evaluation of firmness in fruits is an important quality attribute because it is directly related to their shelf life, since fruit tissue softening is a consequence of their ripening (TOIVONEN; BRUMMELL, 2008). However it is important to highlight that fruit softening in postharvest depends on the softening rate at harvest, according to the Burdon et al. (2014).

For fruits peel coloration, the mean values verified for luminosity, color angle (Hue) and

chromaticity were 50.98; 86.18 and 31.24, respectively. The Hue angle indicates the fruit color itself, and according to the values obtained for the 'Taquari', it was concluded that the fruit presented peel coloration from red to yellow (Hue 86.18 ± 12.1). For the values detected for fruit pulp, a more yellowish pulp coloration was verified (Hue 88.76 ± 1.8) with elevated pigment saturation (Chromaticity 57.12 ± 1.6). The modification in fruit peel and pulp coloration is a consequence of the ripening of fruits, and this criterion has been used for timing harvest (Pinto et al., 2013). The mean values detected for the contents of soluble solids and titrable acidity were 18 °Brix and 1.0 g citric acid 100 g^{-1} , respectively (Table 14). These contents in the fruit can vary according to the cultivar, and are important to evaluate fruit maturation. In general during fruit maturation the soluble solids contents tend to increase, whereas titrable acidity decreases (SOUZA et al., 2011). FISCHER et al. (2009), characterizing ripe mangoes from cultivars Haden, Tommy Atkins, Palmer and Keitt, registered values

between 14.88 and 18% of soluble solids, and 0.1 to 0.8% of citric acid.

The mean value obtained for fruit pulp pH was 3.2 (Table 14). The lower pH values found for most of the fruit disfavors bacterial growth; conversely, molds and yeasts are more tolerant to environments of low pH (CHITARRA; CHITARRA, 2005).

The mean ascorbic acid content registered in this work for the 'Taquari' fruits was 63.12 mg of ascorbic acid 100 g^{-1} (Table 14), considering a high content in mangoes when compared to some varieties studied by other authors, such as in 'Palmer', 37.27 mg 100 g^{-1} (SANTOS et al., 2010), 'Tommy Atkins', 13.5 mg 100 g^{-1} (SOUZA et al., 2011) and 'Haden', 16.52 mg 100 g^{-1} (ALBUQUERQUE et al., 2011). The ascorbic acid is an antioxidant compound synthesized by the vegetables in amounts that vary according to, among other factors, cultivar and maturation degree, and tend to decrease with fruit ripening, because of oxidative reactions (NEVES et al., 2008).

Table 14. Physical and quality characterization of 'Taquari' harvested at the mature ripening process.

Parameter	Maturation stage
	Mature
Fruit weight (g)	986.67±70
Firmness (N)	18.04±6.4
Peel luminosity	50.98±5.5
Peel Hue angle	86.18±12.1
Peel chromaticity	31.24±4.1
Pulp luminosity	70.54±0.6
Pulp Hue angle	88.76±1.8
Pulp chromaticity	57.12±1.6
Soluble solids (°Brix)	18±2.9
Titrable acidity (g citric acid 100 g^{-1})	1.006±0.10
pH	3.2±0.3
Ascorbic acid (mg ascorbic acid 100 g^{-1})	63.124±3.5
CO ₂ (ml CO ₂ $\text{kg}^{-1} \text{ h}^{-1}$)	31.10±8.3

Mean of 3 repetitions with 4 fruit each.

The mean respiratory rate of the fruit was registered as 31.10 ml CO₂ $\text{kg}^{-1} \text{ h}^{-1}$ (Table 14). The fruits classified as climacteric, such as mango, after harvested and stored under conditions of room temperature, may present a rapid increase in the

respiratory rate, subsequently starting the ripening process (CHITARRA; CHITARRA, 2005). Climacteric respiration peak of 'Tommy Atkins' mangoes was reached nine days after harvest, in work completed by Alves et al. (2004).

Nevertheless, in the present work the fruit were harvested at the mature ripening process, which means the climacteric peak occurred before harvest.

CONCLUSIONS

'Taquari' fruits presents fruit with medium size and elongated shape, resembling 'Palmer' fruits, as well as an attractive coloration of pulp and peel.

It is also concluded that there is a better seedling emergence in the absence of seed coat in 'Taquari' fruits, however with a higher occurrence of polyembryony.

The fruit of 'Taquari' tree present quality characteristics, such as soluble solids and titrable acidity, similar to those of the main cultivars currently commercialized in the country, but with an emphasis for the high ascorbic acid contents found in these fruit, compared to cultivars of commercial importance.

RESUMO: Os frutos da mangueira 'Taquari' têm aparência atrativa, com polpa amarelo intenso, sabor agradável e ausência de fibras, o que a torna um material com grande potencial para futuramente ser lançado como variedade. Com o objetivo de avaliar caracteres fenotípicos relativos emergência, biometria e pós-colheita, do material 'Taquari' este trabalho foi desenvolvido. Para a biometria foram utilizados 50 frutos maduros, os resultados foram avaliados por estatística descritiva, utilizando-se de medida de tendência central (média) e de variabilidade de dados (desvio-padrão). Para o teste de germinação, as sementes foram extraídas de frutos maduros e colocadas para secar, em seguida, foram colocadas para germinar em saquinhos contendo como substrato mistura de solo:areia:estercos de curral curtido (3:1:1), avaliando-se a emergência das plântulas e a poliembrião. O delineamento foi em blocos casualizados e foram estudados 5 tratamentos, com 5 repetições cada e 10 sementes por repetição. Os dados de porcentagem foram transformados em arc-sen, submetidos à análise de variância e as médias ao teste Tukey a 5% de probabilidade. Para a caracterização de qualidade dos frutos, utilizaram-se 12 frutos maduros, separadas em 3 lotes com 4 frutos, utilizando delineamento inteiramente casualizado. Os frutos foram caracterizados quanto a firmeza, coloração de casca e polpa, sólidos solúveis, acidez titulável, pH, ácido ascórbico e taxa respiratória. Conclui-se que a mangueira 'Taquari' apresenta frutos com características interessantes para o mercado brasileiro e há melhor emergência das plântulas na ausência do tegumento da semente, porém com maior ocorrência de poliembrião. Para a caracterização de qualidade, os frutos apresentam parâmetros como de sólidos solúveis e acidez titulável similares às principais cultivares de mangas comercializadas no país, porém com destaque para os altos teores de ácido ascórbico encontrados.
